2.2 Cells and Floors

For $x, y \in \mathbb{R}$, $m, n \in \mathbb{Z}$:

- $\lfloor x \rfloor \leq x < \lfloor x \rfloor + 1$; $\lceil x \rceil - 1 < x \leq \lceil x \rceil$
- $-\lfloor x \rfloor = \lceil -x \rceil$; $-\lceil x \rceil = \lfloor -x \rfloor$
- $\lfloor x + n \rfloor = \lfloor x \rfloor + n$, $\lceil x + n \rceil = \lceil x \rceil + n$
- $\lfloor x \rfloor = m \Leftrightarrow x - 1 < m \leq x < m + 1$
- $\lceil x \rceil = n \Leftrightarrow n - 1 < x \leq n < x + 1$
- If $n > 0$, $\lfloor \frac{\lfloor x \rfloor + m}{n} \rfloor = \lfloor \frac{x + m}{n} \rfloor$
- If $n > 0$, $\lceil \frac{\lceil x \rceil + m}{n} \rceil = \lceil \frac{x + m}{n} \rceil$
- If $n > 0$, $\lfloor \frac{\lfloor x \rfloor - m}{n} \rfloor = \lfloor \frac{x - m}{n} \rfloor$
- If $n > 0$, $\lceil \frac{\lceil x \rceil - m}{n} \rceil = \lceil \frac{x - m}{n} \rceil$
- For $m, n > 0$, $\sum_{k=1}^{n-1} \lfloor \frac{km}{n} \rfloor = \frac{(m-1)(n-1)+\gcd(m,n)-1}{2}$

2.3 Recurrences

If $a_n = c_1 a_{n-1} + \dots + c_k a_{n-k}$, and r_1, \dots, r_k are distinct roots of $x^k - c_1 x^{k-1} - \dots - c_k$, there are d_1, \dots, d_k s.t.

$$a_n = d_1 r_1^n + \dots + d_k r_k^n.$$

Non-distinct roots r become polynomial factors, e.g. $a_n = (d_1 n + d_2) r^n$.

2.4 Trigonometry

$$\sin(v+w) = \sin v \cos w + \cos v \sin w$$

$$\cos(v+w) = \cos v \cos w - \sin v \sin w$$

$$\tan(v+w) = \frac{\tan v + \tan w}{1 - \tan v \tan w}$$

$$\sin v + \sin w = 2 \sin \frac{v+w}{2} \cos \frac{v-w}{2}$$

$$\cos v + \cos w = 2 \cos \frac{v+w}{2} \cos \frac{v-w}{2}$$

$$(V+W) \tan(\frac{v-w}{2}) = (V-W) \tan(\frac{v+w}{2})$$

V, W are sides opposite to angles v, w .

$$a \cos x + b \sin x = r \cos(x - \phi)$$

$$a \sin x + b \cos x = r \sin(x + \phi)$$

where $r = \sqrt{a^2 + b^2}$, $\phi = \text{atan2}(b, a)$.

Mathematics (2)

2.1 Equations

The extremum of a quadratic is given by $x = -b/2a$.

Cramer: Given an equation $Ax = b$, the solution to a variable x_i is given by

$$x_i = \frac{\det A'_i}{\det A} \quad [\text{where } A'_i \text{ is } A \text{ with the } i\text{'th column replaced by } b.]$$

Vieta: Let $P(x) = a_n x^n + \dots + a_0$, be a polynomial with complex coefficients and degree n , having complex roots r_n, \dots, r_1 . Then for any integer $0 \leq k \leq n$,

$$\sum_{1 \leq i_1 < i_2 < \dots < i_k \leq n} r_{i_1} r_{i_2} \dots r_{i_k} = (-1)^k \frac{a_{n-k}}{a_n}$$

Rational Root Theorem: If $\frac{p}{q}$ is a reduced rational root of a polynomial with **integer coeffs**, then $p \mid a_0$ and $q \mid a_n$

2.5 Geometry

2.5.1 Triangles

Side lengths: a, b, c

$$\text{Semiperimeter: } p = \frac{a+b+c}{2}$$

$$\text{Area: } A = \sqrt{p(p-a)(p-b)(p-c)}$$

$$\text{Circumradius: } R = \frac{abc}{4A}$$

$$\text{Inradius: } r = \frac{A}{p}$$

Length of median (divides triangle into two equal-area triangles):

$$m_a = \frac{1}{2}\sqrt{2b^2 + 2c^2 - a^2}$$

Length of bisector (divides angles in two):

$$s_a = \sqrt{bc[1 - (a/(b+c))^2]}$$

Law of sines, cosines & tangents:

$$\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c} = \frac{1}{2R} \dots \dots (1)$$

$$a^2 = b^2 + c^2 - 2bc \cos \alpha \dots \dots (2)$$

$$\frac{a+b}{a-b} = \frac{\tan((\alpha+\beta)/2)}{\tan((\alpha-\beta)/2)} \dots \dots (3)$$

2.5.2 Quadrilaterals

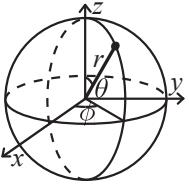

With side lengths a, b, c, d , diagonals e, f , diagonals angle θ , area A and magic flux $F = b^2 + d^2 - a^2 - c^2$:

$$4A = 2ef \cdot \sin \theta = F \tan \theta = \sqrt{4e^2f^2 - F^2}$$

For cyclic quadrilaterals the sum of opposite angles is 180° , $ef = ac + bd$, and

$$A = \sqrt{(p-a)(p-b)(p-c)(p-d)}$$

2.5.3 Spherical coordinates

$$\begin{aligned} x &= r \sin \theta \cos \phi & r &= \sqrt{x^2 + y^2 + z^2} \\ y &= r \sin \theta \sin \phi & \theta &= \arccos(z/\sqrt{x^2 + y^2 + z^2}) \\ z &= r \cos \theta & \phi &= \text{atan2}(y, x) \end{aligned}$$

2.6 Derivatives/Integrals

$$\begin{aligned} \frac{d}{dx} \arcsin x &= \frac{1}{\sqrt{1-x^2}} & \frac{d}{dx} \arccos x &= -\frac{1}{\sqrt{1-x^2}} \\ \frac{d}{dx} \tan x &= 1 + \tan^2 x & \frac{d}{dx} \arctan x &= \frac{1}{1+x^2} \\ \int \tan ax \, dx &= -\frac{\ln |\cos ax|}{a} & \int xe^{ax} \, dx &= \frac{e^{ax}}{a^2}(ax-1) \\ \int e^{-x^2} \, dx &= \frac{\sqrt{\pi}}{2} \operatorname{erf}(x) & \int x \sin ax \, dx &= \frac{\sin ax - ax \cos ax}{a^2} \end{aligned}$$

$$\int_a^b f(x)g(x)dx = [F(x)g(x)]_a^b - \int_a^b F(x)g'(x)dx$$

2.7 Sums

$$c^a + c^{a+1} + \dots + c^b = \frac{c^{b+1} - c^a}{c-1}, c \neq 1$$

$$1^4 + 2^4 + 3^4 + \dots + n^4 = S_2 \times \frac{3n^2 + 3n - 1}{5} = S_4$$

$$b \sum_{k=0}^{n-1} (a + kd)r^k = \frac{ab - (a + nd)br^n}{1-r} + \frac{dbr(1-r^n)}{(1-r)^2}$$

To compute $1^k + \dots + n^k$ in $\mathcal{O}(k \lg k + k \lg MOD)$ compute first $t = k + 2$ sums y_1, \dots, y_t , then interpolate. Let $P = \prod_{i=1}^t (n-i)$. Then answer for n is

$$\sum_{i=1}^t \frac{P}{n-i} \cdot \frac{(-1)^{t-i} y_i}{(i-1)!(t-i)!}$$

Also $S_k = \frac{1}{k+1} \sum_{j=0}^k (-1)^j \binom{k+1}{j} B_j n^{k+1-j}$ where B_j are Bernoulli numbers.

2.8 Series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots, (-\infty < x < \infty)$$

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots, (-1 < x \leq 1)$$

$$\sqrt{1+x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{2x^3}{32} - \frac{5x^4}{128} + \dots, (-1 \leq x \leq 1)$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots, (-\infty < x < \infty)$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots, (-\infty < x < \infty)$$

$$(1-x)^{-r} = \sum_{i=0}^{\infty} \binom{r+i-1}{i} x^i, (r \in \mathbb{R})$$

2.9 Bitwise Formulas

$$a|b = a \oplus b + a \& b$$

$$\begin{aligned} a \oplus (a \& b) &= (a|b) \oplus b & a \oplus b &= (a \& b) \oplus (a|b) \\ a + b &= a|b + a \& b & a + b &= a \oplus b + 2(a \& b) \end{aligned}$$

$$\begin{aligned} a - b &= (a \oplus (a \& b)) - ((a|b) \oplus a) = \\ &((a|b) \oplus b) - ((a|b) \oplus a) = (a \oplus (a \& b)) - (b \oplus (a \& b)) = \\ &((a|b) \oplus b) - (b \oplus (a \& b)) \end{aligned}$$

2.10 Probability theory

Let X be a discrete random variable with probability $p_X(x)$ of assuming the value x . It will then have an expected value (mean) $\mu = \mathbb{E}(X) = \sum_x x p_X(x)$ and variance $\sigma^2 = V(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2 = \sum_x (x - \mathbb{E}(X))^2 p_X(x)$ where σ is the standard deviation. If X is instead continuous it will have a probability density function $f_X(x)$ and the sums above will instead be integrals with $p_X(x)$ replaced by $f_X(x)$.

Expectation is linear:

$$\mathbb{E}(aX + bY) = a\mathbb{E}(X) + b\mathbb{E}(Y)$$

For independent X and Y ,

$$V(aX + bY) = a^2 V(X) + b^2 V(Y).$$

2.10.1 Discrete distributions

Binomial distribution

The number of successes in n independent yes/no experiments, each which yields success with probability p is

$$\text{Bin}(n, p), n = 1, 2, \dots, 0 \leq p \leq 1.$$

$$p(k) = \binom{n}{k} p^k (1-p)^{n-k}$$

$$\mu = np, \sigma^2 = np(1-p)$$

$\text{Bin}(n, p)$ is approximately $\text{Po}(np)$ for small p .

First success distribution

The number of trials needed to get the first success in independent yes/no experiments, each which yields success with probability p is $\text{Fs}(p), 0 \leq p \leq 1$.

$$p(k) = p(1-p)^{k-1}, k = 1, 2, \dots$$

$$\mu = \frac{1}{p}, \sigma^2 = \frac{1-p}{p^2}$$

Poisson distribution

The number of events occurring in a fixed period of time t if these events occur with a known average rate κ and independently of the time since the last event is $\text{Po}(\lambda), \lambda = t\kappa$.

$$p(k) = e^{-\lambda} \frac{\lambda^k}{k!}, k = 0, 1, 2, \dots$$

$$\mu = \lambda, \sigma^2 = \lambda$$

2.10.2 Continuous distributions

Uniform distribution

If the probability density function is constant between a and b and 0 elsewhere it is $\text{U}(a, b), a < b$.

$$f(x) = \begin{cases} \frac{1}{b-a} & a < x < b \\ 0 & \text{otherwise} \end{cases}$$

$$\mu = \frac{a+b}{2}, \sigma^2 = \frac{(b-a)^2}{12}$$

Exponential distribution

The time between events in a Poisson process is $\text{Exp}(\lambda), \lambda > 0$.

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & x \geq 0 \\ 0 & x < 0 \end{cases}$$

$$\mu = \frac{1}{\lambda}, \sigma^2 = \frac{1}{\lambda^2}$$

Normal distribution

Most real random values with mean μ and variance σ^2 are well described by $\mathcal{N}(\mu, \sigma^2), \sigma > 0$.

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

If $X_1 \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and $X_2 \sim \mathcal{N}(\mu_2, \sigma_2^2)$ then

$$aX_1 + bX_2 + c \sim \mathcal{N}(\mu_1 + \mu_2 + c, a^2\sigma_1^2 + b^2\sigma_2^2)$$

2.11 Markov chains

A *Markov chain* is a discrete random process with the property that the next state depends only on the current state. Let X_1, X_2, \dots be a sequence of random variables generated by the Markov process. Then there is a transition matrix $\mathbf{P} = (p_{ij})$, with $p_{ij} = \Pr(X_n = i | X_{n-1} = j)$, and $\mathbf{P}^{(n)} = \mathbf{P}^n \mathbf{P}^{(0)}$ is the probability distribution for X_n (i.e., $p_i^{(n)} = \Pr(X_n = i)$), where $\mathbf{P}^{(0)}$ is the initial distribution.

π is a stationary distribution if $\pi = \pi \mathbf{P}$. If the Markov chain is *irreducible* (it is possible to get to any state from any state), then $\pi_i = \frac{1}{\mathbb{E}(T_i)}$ where $\mathbb{E}(T_i)$ is the expected time between two visits in state i . π_j/π_i is the expected number of visits in state j between two visits in state i .

For a connected, undirected and non-bipartite graph, where the transition probability is uniform among all neighbors, π_i is proportional to node i 's degree.

A Markov chain is *ergodic* if the asymptotic distribution is independent of the initial distribution. A finite Markov chain is ergodic iff it is irreducible and *aperiodic* (i.e., the gcd of cycle lengths is 1). $\lim_{k \rightarrow \infty} \mathbf{P}^k = \mathbf{1}\pi$.

A Markov chain is an *A-chain* if the states can be partitioned into two sets **A** and **G**, such that all states in **A** are absorbing ($p_{ii} = 1$), and all states in **G** leads to an absorbing state in **A**. The probability for absorption in state $i \in \mathbf{A}$, when the initial state is j , is $a_{ij} = p_{ij} + \sum_{k \in \mathbf{G}} a_{ik} p_{kj}$. The expected time until absorption, when the initial state is i , is $t_i = 1 + \sum_{k \in \mathbf{G}} p_{ki} t_k$.

2.12 Trivia

Pythagorean triples: The Pythagorean triples are uniquely generated by $a = k \cdot (m^2 - n^2)$, $b = k \cdot (2mn)$, $c = k \cdot (m^2 + n^2)$ with $m > n > 0$, $k > 0$, $\gcd(m, n) = 1$, both m, n not odd.

Primes: $p = 962592769$ is such that $2^{21} \mid p-1$, which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than 1000 000.

Primitive roots modulo n exists iff $n = 1, 2, 4$ or, $n = p^k, 2p^k$ where p is an odd prime. Furthermore, the number of roots are $\phi(\phi(n))$.

To Find Generator g of M , factor $M-1$ and get the distinct primes p_i . If $g^{(M-1)/p_i} \neq 1(MOD M)$ for each p_i then g is a valid root. Try all g until a hit is found (usually found very quick).

Estimates: $\sum_{d|n} d = O(n \log \log n)$.

Prime count: 5133 upto 5e4. 9592 upto 1e5. 17984 upto 2e5. 78498 upto 1e6. 5761455 upto 1e8.

```

Line &g = dat[k];
if(eval(f, lx) < eval(g, lx) && eval(f, rx)
    < eval(g, rx)) {
    g = f; return;
}
if(eval(f, lx) >= eval(g, lx) && eval(f, rx)
    >= eval(g, rx))
    return;
if(eval(f, mx) < eval(g, mx)) swap(f, g);
if(eval(f, lx) < eval(g, lx)) k = k * 2 +
    1, r = m;
else k = k * 2 + 2, l = m;
}
void add_line(Line f){_add_line(f, 0, 0, n);}
void add_segment(Line f, ll lx, ll rx){
    int l = lower_bound(xl.begin(), xl.end(),
        lx) - xl.begin();
    int r = lower_bound(xl.begin(), xl.end(),

    return min(jmp[dep][a], jmp[dep][b - (1 << dep)]);
}

```

MoTree.h

Description: Build Euler tour of $2N$ size - write node at first enter and last exit. Now, Path(u, v) with $in[u] < in[v]$ is a segment. If $lca(u, v) = u$ then it is $[in[u], in[v]]$. Otherwise it is $[out[u], in[v]] + \text{LCA}$ node. Nodes that appear exactly once in each segment are relevant, ignore others, handle LCA separately.

Time: $\mathcal{O}(Q\sqrt{N})$

MoUpdate.h

Description: Set block size $B = (2n^2)^{1/3}$. Sort queries by $(\lfloor \frac{L}{B} \rfloor, \lfloor \frac{R}{B} \rfloor, t)$, where $t = \text{number of updates before this query}$. Then process queries in sorted order, modify L, R and then apply/undo the updates to answer.

Time: $\mathcal{O}(Bq + qn^2/B^2)$ or $\mathcal{O}(qn^{2/3})$ with that B .

Numerical (4)**4.1 Polynomials and recurrences****BerlekampMassey.h**

Description: Recovers any n -order linear recurrence relation from the first $2n$ terms of the recurrence. Useful for guessing linear recurrences after brute-forcing the first terms. Should work on any field, but numerical stability for floats is not guaranteed. Output will have size $\leq n$.

Usage: berlekampMassey({0, 1, 1, 3, 5, 11}) // {1, 2} --> c[n] = c[n-1] + 2c[n-2]

Time: $\mathcal{O}(N^2)$

"../number-theory/ModPow.h" 96548b, 20 lines

```

        else h = m;
    }
    ret.push_back((l + h) / 2);
}
return ret;
}

```

PolyInterpolate.h

Description: Given n points $(x[i], y[i])$, computes an n -1-degree polynomial p that passes through them: $p(x) = a[0] * x^0 + \dots + a[n-1] * x^{n-1}$. For numerical precision, pick $x[k] = c * \cos(k/(n-1) * \pi)$, $k = 0 \dots n-1$. For fast interpolation in $O(n \log^2 n)$ use Lagrange. $P(x) = \sum_{i=1}^n y_i \prod_{j \neq i} \frac{x-x_j}{x_i-x_j}$. To compute values $\prod_{j \neq i} (x_i - x_j)$ fast, compute $A(x) = \prod_{i=1}^n (x - x_i)$ with divide and conquer. The required values are $A'(x_i)$, (values at derivatives), compute fast with multipoint evaluation.

Time: $\mathcal{O}(n^2)$

08bf48, 13 lines

```

typedef vector<double> vd;

    rep(k, 0, n-1) rep(i, k+1, n)
        y[i] = (y[i] - y[k]) / (x[i] - x[k]);
    double last = 0; temp[0] = 1;
    rep(k, 0, n) rep(i, 0, n) {
        res[i] += y[k] * temp[i];
        swap(last, temp[i]);
        temp[i] -= last * x[k];
    }
    return res;
}

```

4.2 Fourier transforms

Let \mathbb{F} denote some field. Let $\mathbb{P} = \mathbb{F}[x]$ and let $S = \mathbb{F}[[x]]$. Let $A = a_0 + a_1x + \dots + a_nx^n \in \mathbb{P}$ and $B = b_0 + b_1x + \dots + b_mx^m \in \mathbb{P}$.

Naive Division + Remainder of A by B : $O(nm)$ polynomial long division taught in school when $B \neq 0$.

Inverse of A : $A(0) \neq 0 \Rightarrow A^{-1} \in \mathbb{S}$. Let $T \in \mathbb{P}$ be s.t. $T(x^2) = A(x)A(-x)$. Then $A^{-1}(x) \equiv A(-x)/T(x^2) \pmod{x^j}$. To compute $A^{-1}(x) \pmod{x^j}$, we can then recursively $T^{-1}(x) \pmod{x^{\lfloor j/2 \rfloor}}$. Time complexity $O(n + j \log j)$.

Hensel's lemma: Let r be a commutative ring and let $F \in r[x]$ and $a, q_0 \in r$ s.t. $F(q_0) \equiv 0 \pmod{a}$ and $F'(q_0)^{-1} \in r$. Then $F(q_1) \equiv 0 \pmod{a^2}$, where $q_1 \equiv q_0 - \frac{F(q_0)}{F'(q_0)}$ ($\pmod{a^2}$). This is useful in particular when $r = \mathbb{P}$ or $r = \mathbb{S}$.

Inverse of A : Hensel's lemma with $F(P) = A - P^{-1}$. $Q_0 \equiv a_0^{-1} \pmod{x^1}$, $Q_{j+1} \equiv Q_j(2 - AQ_j) \pmod{x^{2j+1}}$. $F(Q_j) \equiv 0 \pmod{x^{2j}}$. Still $O(n + j \log j)$.

Faster Division: Given $P \in \mathbb{P}$, let P^R denote the polynomial with its coefficients reversed. If $A = DB + R$ with $\deg R < \deg B$, then $D^R \equiv A^R/B^R \pmod{x^{n-m+1}}$ and $R = A - BD$. Time complexity $O((n+m) \log(n+m))$.

In A: $(\ln A)' = A'/A$. So $\ln A = Q_0 + \int A'/A$ for some $Q_0 \in \mathbb{F}$. Intuition suggests that $Q_0 = \ln a_0$, since $\ln A(0) = Q_0 = \ln a_0$.

exp A: $Q_{k+1} \equiv Q_k(1 + A - \ln Q_k) \pmod{x^{2^{k+1}}}$.

Aj: Let $T \in \mathbb{P}$ be s.t. $T(0) = 1$ and $A(x) = \alpha x^t T(x)$ for some $\alpha \in k$. Then $A^j(x) = \alpha^j x^{jt} \exp[j \ln T(x)]$.

Chirp-Z: Given $z \in \mathbb{C}$, $s \in \mathbb{N}_{\geq 0}$.

$A(z^{2s}) = z^{s^2} \sum_{j=0}^n (a_j z^j) (z^{-(s-j)^2})$. Clearly, $A(z^0), A(z^2), \dots, A(z^{2s})$ can be computed in one convolution with time complexity $O((s+n) \log(s+n))$. By applying $a_j \mapsto a_j z^j \forall j$, we can then apply the previous algo to compute $A(z^1), A(z^3), \dots, A(z^{2s+1})$ in the same time complexity.

Multipoint-Eval: To calculate

$A(x_0), \dots, A(x_{n-1})$, we use the fact that $\forall i, A(x_i) \equiv A(x) \pmod{x - x_i}$. Segment tree, segment $[l, r]$ has $P_{l,r} = \prod_{j=l}^{r-1} (x - x_j)$. We want $A_{l,r} = (A(x) \pmod{P_{l,r}})$. If $mid = \lfloor (l+r)/2 \rfloor$, then $A_{l,mid} = (A_{l,r} \pmod{P_{l,mid}})$ and $A_{mid,r} = (A_{mid,r} \pmod{P_{mid,r}})$. Finally, $A_{i,i+1} = A(x_i) \forall i$. $O(n \log^2 n)$.

Interpolation: Given $(x_0, y_0), \dots, (x_{n-1}, y_{n-1})$ s.t. x_0, \dots, x_{n-1} are distinct and $\forall i, A(x_i) = y_i$. Then $A(x) = \sum_{i=1}^n y_i \prod_{j \neq i} \frac{x-x_j}{x_i-x_j}$. Let $P(x) = \prod_j (x - x_j)$ and $\forall i, P_i = \prod_{j \neq i} (x_i - x_j)$. Then $P_i = P'(x_i)$, so use multipoint evaluation to compute P_0, \dots, P_{n-1} . Now, we recursively compute $A(x) = A_{0,n}(x)$ by letting $A_{l,r}(x) = A_{l,mid}(x) \prod_{mid \leq j < r} (x - x_j) + A_{mid,r}(x) \prod_{l \leq j < mid} (x - x_j)$. And $\forall i, A_{i,i+1}(x) = \frac{y_i}{P_i}$. Here, $mid = \lfloor (l+r)/2 \rfloor$. $O(n \log^2 n)$.

GCD and Resultants: Let $\lambda_1, \dots, \lambda_n$ and μ_1, \dots, μ_m be the roots of A and B respectively, with multiplicity. Then the resultant $\mathcal{R}(A, B) = a_m^m b_m^m \prod_{i,j} (\mu_j - \lambda_j)$. $\mathcal{R}(A, B) = (-1)^{nm} \mathcal{R}(B, A)$. $\mathcal{R}(A, B) = 0$ iff A and B share a common root. $\mathcal{R}(A, B) = a_n^m b_n^m$ when $n = 0$ or $m = 0$. $\forall C \in k[x], \mathcal{R}(A, C) = b_m^{\deg A - \deg(A-CB)} \mathcal{R}(A - CB, B)$. So, we can compute $\gcd(A, B)$ and $\mathcal{R}(A, B)$ at the same time in $O(mn)$: $\mathcal{R}(A, 0) = 0$, $\mathcal{R}(A, B) = b_m^n$, $\mathcal{R}(A, B) = b_m^{\deg A - \deg D} (-1)^{\deg B \deg D} \mathcal{R}(B, D)$. Here, $D = (A \pmod{B})$. We can use this to find intersection between two curves of the form $P(x, y) = 0$ and $Q(x, y) = 0$. Let $P_{y_0}(x) = P(x, y_0) \in k[x]$ and $Q_{y_0}(x) = Q(x, y_0) \in k[x]$. First, we can solve $R(y_0) = \mathcal{R}(P_{y_0}(x), Q_{y_0}(x)) = 0$ for y_0 . Then for those y_0 , we solve $P(x, y_0) = Q(x, y_0) = 0$. Under simple circumstances, we should get finitely many intersection points.

FastFourierTransform.h

Description: fft(a) computes $\hat{f}(k) = \sum_x a[x] \exp(2\pi i \cdot kx/N)$ for all k . N must be a power of 2. Useful for convolution: $\text{conv}(a, b) = c$, where $c[x] = \sum a[i]b[x-i]$. For convolution of complex numbers or more than two vectors: FFT each poly, multiply result pointwise, divide by n , reverse(out.begin() + 1, end), FFT back, then round(out[i].real()) or truncate out[i].imag(0). Rounding is safe if $(\sum a_i^2 + \sum b_i^2) \log_2 N < 9 \cdot 10^{14}$ (in practice 10^{16} ; higher for random inputs). Otherwise, use NT-T/FFTMod.

Time: $\mathcal{O}(N \log N)$ with $N = |A| + |B|$ ($\sim 1s$ for $N = 32$, $\sim 22s$ for $N = 36$)

```

typedef complex<double> C;

```

NumberTheoreticTransform.h

Description: nt(a) computes $\hat{f}(k) = \sum_x a[x]g^{xk}$ for all k , where $g = \text{root}^{(mod-1)/N}$. N must be a power of 2. Useful for convolution modulo specific nice primes of the form $2^a b + 1$, where the convolution result has size at most 2^a . For arbitrary modulo, see FFTMod. conv(a, b) = c, where $c[x] = \sum a[i]b[x-i]$. For manual convolution: NTT the inputs, multiply pointwise, divide by n, reverse(start+1, end), NTT back. Inputs must be in $[0, \text{mod}]$.

Time: $\mathcal{O}(N \log N)$

}
```

Tridiagonal.h

Description: $x = \text{tridiagonal}(d, p, q, b)$ solves the equation system

$$\begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ \vdots \\ b_{n-1} \end{pmatrix} = \begin{pmatrix} d_0 & p_0 & 0 & 0 & \cdots & 0 \\ q_0 & d_1 & p_1 & 0 & \cdots & 0 \\ 0 & q_1 & d_2 & p_2 & \cdots & 0 \\ 0 & 0 & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & q_{n-3} & d_{n-2} & p_{n-2} \\ 0 & 0 & \cdots & 0 & q_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_{n-1} \end{pmatrix}$$

This is useful for solving problems on the type

$$a_i = b_i a_{i-1} + c_i a_{i+1} + d_i, 1 \leq i \leq n,$$

where a_0, a_{n+1}, b_i, c_i and d_i are known. a can then be obtained from

$$\{a_i\} = \text{tridiagonal}(\{1, -1, -1, \dots, -1, 1\}, \{0, c_1, c_2, \dots, c_n\}, \{b_1, b_2, \dots, b_n, 0\}, \{a_0, d_1, d_2, \dots, d_n, a_{n+1}\}).$$

Fails if the solution is not unique.

If $|d_i| > |p_i| + |q_{i-1}|$ for all i , or $|d_i| > |p_{i-1}| + |q_i|$, or the matrix is positive definite, the algorithm is numerically stable and neither tr nor the check for $\text{diag}[i] == 0$ is needed.

Time: $\mathcal{O}(N)$

        }
    }
    return b;
}
```

4.4 Optimization

GoldenSectionSearch.h

Description: Finds the argument minimizing the function f in the interval $[a, b]$ assuming f is unimodal on the interval, i.e. has only one local minimum and no local maximum. The maximum error in the result is eps . Works equally well for maximization with a small change in the code. See `TernarySearch.h` in the Various chapter for a discrete version.

Usage:

```
double func(double x) { return 4*x+3*x*x; }
double xmin = gss(-1000,1000,func);
Time:  $\mathcal{O}(\log((b-a)/\epsilon))$ 
```

31d45b, 14 lines

```
double gss(double a, double b, double (*f)(double)) {
    double r = (sqrt(5)-1)/2, eps = 1e-7;
    double x1 = b - r*(b-a), x2 = a + r*(b-a);
    double f1 = f(x1), f2 = f(x2);
    while (b-a > eps)
        if (f1 < f2) { //change to > to find
            maximum
            b = x2; x2 = x1; f2 = f1;
            x1 = b - r*(b-a); f1 = f(x1);
        } else {
            a = x1; x1 = x2; f1 = f2;
            x2 = a + r*(b-a); f2 = f(x2);
        }
    return a;
}
```

HillClimbing.h

Description: Poor man's optimization for unimodal functions.

seeef, 14 lines

```
typedef array<double, 2> P;

template<class F> pair<double, P> hillClimb(P start, F f) {
    pair<double, P> cur(f(start), start);

        rep(j, 0, 100) rep(dx, -1, 2) rep(dy, -1, 2) {
            P p = cur.second;
            p[0] += dx*jmp;
            p[1] += dy*jmp;
            cur = min(cur, make_pair(f(p), p));
        }
    }
    return cur;
}
```

Integrate.h

Description: Simple integration of a function over an interval using Simpson's rule. The error should be proportional to h^4 , although in practice you will want to verify that the result is stable to desired precision when epsilon changes.

4756fc, 7 lines

```
template<class F>
double quad(double a, double b, F f, const int n = 1000) {
    double h = (b - a) / 2 / n, v = f(a) + f(b);
    rep(i, 1, n*2)
        v += f(a + i*h) * (i&1 ? 4 : 2);
    return v * h / 3;
}
```

IntegrateAdaptive.h

Description: Fast integration using an adaptive Simpson's rule.

Usage:

```
double sphereVolume = quad(-1, 1,
[](double x) {
    return quad(-1, 1, [&](double y) {
        return quad(-1, 1, [&](double z) {
            return x*x + y*y + z*z < 1; });
    });
});
```

```
typedef double d;
#define S(a,b) (f(a) + 4*f((a+b)/2) + f(b))
             * (b-a) / 6
```

template <class F>

```
d rec(F& f, d a, d b, d eps, d S) {
    d c = (a + b) / 2;
    d S1 = S(a, c), S2 = S(c, b), T = S1 + S2;
    if (abs(T - S) <= 15 * eps || b - a < 1e-10)
        return T + (T - S) / 15;
    return rec(f, a, c, eps / 2, S1) + rec(f, c,
                                             b, eps / 2, S2);
}
```

template<class F>

```
d quad(d a, d b, F f, d eps = 1e-8) {
    return rec(f, a, b, eps, S(a, b));
}
```

Simplex.h

Description: Solves a general linear maximization problem: maximize $c^T x$ subject to $Ax \leq b$, $x \geq 0$. Returns -inf if there is no solution, inf if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.

Usage:

```
vvd A = {{1,-1}, {-1,1}, {-1,-2}};
vd b = {1,1,-4}, c = {-1,-1}, x;
T val = LPSolver(A, b, c).solve(x);
Time:  $\mathcal{O}(NM * \# \text{pivots})$ , where a pivot may be e.g. an edge relaxation.  $\mathcal{O}(2^n)$  in the general case.
```

aa8530, 68 lines

}

```

CRT.h

Description: Chinese Remainder Theorem.

$\text{ crt}(a, m, b, n)$ computes x such that $x \equiv a \pmod{m}$, $x \equiv b \pmod{n}$. If $|a| < m$ and $|b| < n$, x will obey $0 \leq x < \text{lcm}(m, n)$. Assumes $mn < 2^{62}$.

Time: $\log(n)$

"euclid.h" 04d93a, 7 lines

```

11 crt(ll a, ll m, ll b, ll n) {
    if (n > m) swap(a, b), swap(m, n);
    ll x, y, g = euclid(m, n, x, y);
    assert((a - b) % g == 0); // else no
        solution
    x = (b - a) % n * x % n / g * m + a;
    return x < 0 ? x + m*n/g : x;
}

```

5.3.1 Bézout's identity

For $a \neq b \neq 0$, then $d = \gcd(a, b)$ is the smallest positive integer for which there are integer solutions to $ax + by = d$. If (x, y) is one solution, then all solutions are given by $(x + kb/d, y - ka/d)$, $k \in \mathbb{Z}$. Find one solution using egcd.

5.4 Fractions

FracBinarySearch.h

Description: Given f and N , finds the smallest fraction $p/q \in [0, 1]$ such that $f(p/q)$ is true, and $p, q \leq N$. You may want to throw an exception from f if it finds an exact solution, in which case N can be removed.

Usage: $\text{fracBS}(\{\}) (\text{Frac } f) \{ \text{return } f.p >= 3 * f.q; \}, 10); // \{1, 3\}$

Time: $\mathcal{O}(\log(N))$

27ab3e, 25 lines

```
struct Frac { ll p, q; };

template<class F>
Frac fracBS(F f, ll N) {

```

```

    bool dir = 1, A = 1, B = 1;
    Frac lo{0, 1}, hi{1, 1}; // Set hi to 1/0 to
        search (0, N)
    if (f(lo)) return lo;
    assert(f(hi));
    while (A || B) {
        ll adv = 0, step = 1; // move hi if dir,
            else lo
        for (int si = 0; step; (step *= 2) >>= si)
            {
                adv += step;
                Frac mid{lo.p * adv + hi.p, lo.q * adv +
                    hi.q};
                if (abs(mid.p) > N || mid.q > N || dir
                    == !f(mid)) {
                    adv -= step; si = 2;
                }
            }
        hi.p += lo.p * adv;
        hi.q += lo.q * adv;
        dir = !dir;
        swap(lo, hi);
        A = B; B = !adv;
    }
    return dir ? hi : lo;
}

```

5.5 Möbius Function

$$\mu(n) = \begin{cases} 0 & n \text{ is not square free} \\ 1 & n \text{ has even number of prime factors} \\ -1 & n \text{ has odd number of prime factors} \end{cases}$$

Mobius Inversion:

$$g(n) = \sum_{d|n} f(d) \Leftrightarrow f(n) = \sum_{d|n} \mu(d)g(n/d)$$

Other useful formulas/forms:

$$\sum_{d|n} \mu(d) = [n = 1], \phi(n) = \sum_{d|n} \mu(d) \frac{n}{d}$$

$$g(n) = \sum_{n|d} f(d) \Leftrightarrow f(n) = \sum_{n|d} \mu(\frac{d}{n})g(d)$$

$$g(n) = \sum_{1 \leq m \leq n} f(\lfloor \frac{n}{m} \rfloor) \Leftrightarrow f(n) = \sum_{1 \leq m \leq n} \mu(m)g(\lfloor \frac{n}{m} \rfloor)$$

If f multiplicative,
 $\sum_{d|n} \mu(d)f(d) = \prod_{\text{prime } p|n} (1 - f(p))$ and
 $\sum_{d|n} u^2(d)f(d) = \prod_{\text{prime } p|n} (1 + f(p)).$

If $s_f(n) = \sum_{i=1}^n f(i)$ is a prefix sum of multiplicative f then $s_{f*g}(n) = \sum_{1 \leq xy \leq n} f(x)g(y).$
 Then $s_f(n) = \{s_{f*g}(n) - \sum_{d=2}^n s_f(\lfloor n/d \rfloor)g(d)\}/g(1)$ where $f*g(n) = \sum_{d|n} f(d)g(n/d)$ (Dirichlet).
 Precompute (linear sieve) $O(n^{2/3})$ first values of s_f for complexity $O(n^{2/3}).$

Useful sums and convolutions: $\epsilon = \mu * \mathbf{1}$, $\text{id} = \phi * \mathbf{1}$, $\text{id} = g * \text{id}_2$, where $\epsilon(n) = [n = 1]$, $\mathbf{1}(n) = 1$, $\text{id}(n) = n$, $\text{id}_k(n) = n^k$, $g(n) = \sum_{d|n} \mu(d)nd.$

coprime pairs in $[1, n]$ is $\sum_{d=1}^n \mu(d)[n/d]^2$. Sum of GCD pairs in $[1, n]$ is $\sum_{d=1}^n \phi(d)[n/d]^2$. Sum of LCM pairs in $[1, n]$ is $\sum_{d=1}^n (\frac{\lfloor n/d \rfloor (1+\lfloor n/d \rfloor)}{2})^2 g(d)$, where g is defined above with $g(p^k) = p^k - p^{k+1}.$

Combinatorial (6)

6.1 Permutations

IntPerm.h

Description: Permutation -> integer conversion. (Not order preserving.) Integer -> permutation can use a lookup table.

Time: $\mathcal{O}(n)$

044568, 6 lines

```
int permToInt(vi& v) {
    int use = 0, i = 0, r = 0;
    for (int x:v) r = r * ++i +
        _builtin_popcount(use & -(1<<x)),
        use |= 1 << x; // (note: minus, not ~!)
    return r;
}
```

multinomial.h

Description: Computes $\binom{v_0 + \dots + v_{n-1}}{v_0, \dots, v_{n-1}}$

a0a312, 6 lines

```
ll multinomial(vi& v) {
    ll c = 1, m = v.empty() ? 1 : v[0];
    rep(i, 1, sz(v)) rep(j, 0, v[i])
        c = c * ++m / (j+1);
    return c;
}
```

Cycles Let $g_S(n)$ be the number of n -permutations whose cycle lengths all belong to the set S . Then

$$\sum_{n \geq 0} g_S(n) \frac{x^n}{n!} = \exp \left(\sum_{n \in S} \frac{x^n}{n} \right)$$

Derangements Permutations of a set such that none of the elements appear in their original position. $D(n) = (n-1)(D(n-1) + D(n-2))$

$$nD(n-1) + (-1)^n = \left\lfloor \frac{n!}{e} \right\rfloor$$

IntPerm multinomial BellmanFord FloydWarshall Johnson Dinic

Burnside's Lemma Given a group G of symmetries and a set X , the number of elements of X up to symmetry equals $\frac{1}{|G|} \sum_{g \in G} |X^g|$, where X^g are the elements fixed by g ($g.x = x$). If $f(n)$ counts “configurations” (of some sort) of length n , we can ignore rotational symmetry using $G = \mathbb{Z}_n$ to get $g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n, k)) = \frac{1}{n} \sum_{k|n} f(k)\phi(n/k).$

Partition function Number of ways of writing n as a sum of positive integers, disregarding the order of the summands. $p(0) = 1$, $p(n) = \sum_{k \in \mathbb{Z} \setminus \{0\}} (-1)^{k+1} p(n-k(3k-1)/2).$

$p(n) \sim 0.145/n \cdot \exp(2.56\sqrt{n})$
 First few values: 1, 1, 2, 3, 5, 7, 11, 15, 22, 30.
 $p(20) = 627$, $p(50) \approx 2e5$, $p(100) \approx 2e8$.

Lucas' Theorem: Let n, m be non-negative integers and p a prime. Write $n = n_k p^k + \dots + n_1 p + n_0$ and $m = m_k p^k + \dots + m_1 p + m_0$. Then $\binom{n}{m} \equiv \prod_{i=0}^k \binom{n_i}{m_i} \pmod{p}.$

Bernoulli numbers EGF of Bernoulli numbers is $B(t) = \frac{t}{et-1}$ (FFT-able). $\sum \frac{B_i}{i!} x^i = \frac{x}{1-e^{-x}}.$
 $B[0, \dots] = [1, -\frac{1}{2}, \frac{1}{6}, 0, -\frac{1}{30}, 0, \frac{1}{42}, \dots].$
 Sums of powers:

$$\sum_{i=1}^n n^m = \frac{1}{m+1} \sum_{k=0}^m \binom{m+1}{k} B_k \cdot (n+1)^{m+1-k}$$

Stirling numbers of the first kind Number of permutations on n items with k cycles.

$$c(n, k) = c(n-1, k-1) + (n-1)c(n-1, k),$$
 $c(0, 0) = 1, \sum_{k=0}^n c(n, k)x^k = x(x+1)\dots(x+n-1)$
 $c(8, k) = 8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1$
 $c(n, 2) = 0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, \dots$

Stirling numbers of the second kind Partitions of n distinct elements into exactly k non-empty subsets. $S(n, k) = S(n-1, k-1) + kS(n-1, k).$

$$S(n, 1) = S(n, n) = 1.$$

$$S(n, k) = \frac{1}{k!} \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n.$$

Eulerian numbers Number of n -permutations with exactly k rises (positions i with $p_i > p_{i-1}$).

$$E(n, k) = (n-k)E(n-1, k-1) + (k+1)E(n-1, k).$$
 $E(n, 0) = E(n, n-1) = 1.$

$$E(n, k) = \sum_{j=0}^k (-1)^j \binom{n+1}{j} (k+1-j)^n.$$

Bell numbers Total number of partitions of n distinct elements. $B(n) =$

$$1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \dots$$

$B(3) = 5 = \{a|b|c, a|bc, b|ac, c|ab, abc\}.$ For p prime, $B(p^m + n) \equiv mB(n) + B(n+1) \pmod{p}.$

Catalan numbers

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \binom{2n}{n} - \binom{2n}{n+1} = \frac{(2n)!}{(n+1)!n!}$$

$$C_0 = 1, C_{n+1} = \frac{2(2n+1)}{n+2} C_n, C_{n+1} = \sum C_i C_{n-i}$$

$$C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786,$$

- UR path from $(0, 0)$ to (n, n) below $y = x$.
 - strings with n pairs of parenthesis, correctly nested.

- binary trees with $n+1$ leaves (0 or 2 children).

- ordered trees with $n+1$ vertices.

- ways a convex polygon with $n+2$ sides can be cut into triangles by connecting vertices with straight lines.

- permutations of $[n]$ with no 3-term increasing subseq.

Labeled unrooted trees: # on n vertices:

$$n^{n-2}$$

on k existing trees of size n_i :

$$n_1 n_2 \cdots n_k n^{k-2}$$

with degrees d_i :

$$(n-2)!/(d_1-1) \cdots (d_n-1)!$$

ways to connect k components with $k-1$ edges:

$$s_1 \cdots s_k \cdot n^{k-2}$$

Number of Spanning Trees Create an $N \times N$ matrix mat , and for each edge $a \rightarrow b \in G$, do

$\text{mat}[a][b]--$, $\text{mat}[b][b]++$ (and $\text{mat}[b][a]--$, $\text{mat}[a][a]++$ if G is undirected). Remove the i th row and column and take the determinant; this yields the number of directed spanning trees rooted at i (if G is undirected, remove any row/column).

Erdős–Gallai theorem A simple graph with node degrees $d_1 \geq \dots \geq d_n$ exists iff $d_1 + \dots + d_n$ is even and for every $k = 1 \dots n$,

$$\sum_{i=1}^k d_i \leq k(k-1) + \sum_{i=k+1}^n \min(d_i, k).$$

Sprague–Grundy Theorem: Viewing the game as a DAG, where a player moves from one node v to any neighbor v_i , the grundy value $G(v) = \text{mex}\{v_i\}$ gives an equivalent pile of nim. If the game breaks into several equivalent games where player can move at any single part, take xorsum to combine (just like nim). Use DP/pattern hunting.

Graph (7)

7.1 Shortest Paths

BellmanFord.h

Description: Calculates shortest paths from s in a graph that might have negative edge weights. Unreachable nodes get $\text{dist} = \text{inf}$; nodes reachable through negative-weight cycles get $\text{dist} = -\text{inf}$. Assumes $V^2 \max|w_i| < \sim 63$.

Time: $\mathcal{O}(VE)$

830a8f, 23 lines

```
const ll inf = LLONG_MAX;
struct Ed { int a, b, w, s(); { return a < b ? a : -a; } };
struct Node { ll dist = inf; int prev = -1; };
```

```
void bellmanFord(vector<Node>& nodes, vector<Ed>& eds, int s) {
    nodes[s].dist = 0;
    sort(all(eds), [](Ed a, Ed b) { return a.s() < b.s(); });
    ...
```

```
    int lim = sz(nodes) / 2 + 2; // /3+100 with shuffled vertices
    rep(i, 0, lim) for (Ed ed : eds) {
```

```
        if (ed.a == s) nodes[ed.b].dist = min(nodes[ed.b].dist, nodes[ed.a].dist + ed.w);
        if (nodes[ed.b].dist == -inf) nodes[ed.b].dist = inf;
    }
```

```
    rep(i, 0, lim) for (Ed ed : eds) {
```

```
        if (ed.b == s) nodes[ed.a].dist = min(nodes[ed.a].dist, nodes[ed.b].dist + ed.w);
        if (nodes[ed.a].dist == -inf) nodes[ed.a].dist = inf;
    }
```

FloydWarshall.h

Description: Calculates all-pairs shortest path in a directed graph that might have negative edge weights. Input is an distance matrix m , where $m[i][j] = \text{inf}$ if i and j are not adjacent. As output, $m[i][j]$ is set to the shortest distance between i and j , inf if no path, or $-\text{inf}$ if the path goes through a negative-weight cycle.

Time: $\mathcal{O}(N^3)$

531245, 12 lines

```
const ll inf = 1LL << 62;
void floydWarshall(vector<vector<ll>>& m) {
    int n = sz(m);
    rep(i, 0, n) m[i][i] = min(m[i][i], 0LL);
    rep(k, 0, n) rep(i, 0, n) rep(j, 0, n)
        if (m[i][k] != inf & m[k][j] != inf) {
            auto newDist = max(m[i][k] + m[k][j], -inf);
            m[i][j] = min(m[i][j], newDist);
        }
    rep(k, 0, n) if (m[k][k] < 0) rep(i, 0, n) rep(j, 0, n)
        if (m[i][k] != inf & m[k][j] != inf) m[i][j] = -inf;
}
```

Johnson.h

Description: APSP on weighted directed graphs with no negative cycles. Add a dummy node q connected by 0-weighted edge to each other node. Then run Bellman from q to find minimum weight $h(v)$ of a path $q \rightsquigarrow v$ (terminate if negative cycle found). Next, reweight the original graph: $\forall u \rightarrow v$ with weight $w(u, v) + h(u) - h(v)$. Now $D(u, v) = \text{Dijkstra}(u, v) + h(v) - h(u)$.

Time: $\mathcal{O}(\text{Bellman}) + \mathcal{O}(V) * \mathcal{O}(\text{Dijkstra})$

7.2 Network flow

Dinic.h

Description: Flow algorithm. with complexity

Time: $\mathcal{O}(VE \log U)$ where $U = \max|\text{cap}|$. $\mathcal{O}(\min(E^{1/2}, V^{2/3})E)$ if $U = 1$; $\mathcal{O}(\sqrt{VE})$ for bipartite matching.

7.2.1 Flow Variations

Demand Flow: Each node has an associated $d(v) = f_{in}(v) - f_{out}(v)$. So $d(v) > 0$ means node wishes to receive more. Given $d(v)$'s for each vertex the problem is to figure out whether it is possible to satisfy all demands while maintaining capacity constraints. Solution - First check $\sum d(v) = 0$. Next add a source S $\rightarrow v$ with capacity $-d(v)$, and for each $d(v) > 0$, add edge $v \rightarrow T$ with capacity $d(v)$. Now $\text{maxflow} = \sum_{d(v)>0} d(v)$ guarantees that solution exists.

Circulations with demands and lower bounds: Each edge now has a lower bound $l(e)$, so the capacity constraint is now $0 \leq l(e) \leq f(e) \leq c(e)$.

Also, each vertex has demand $d(v)$. Solution - Split flow into two parts f_0, f_1 . Let $f_0(e) = l(e)$ for each edge, thus the lower bound condition is satisfied.

Now satisfy the demand conditions by setting new demand $d'(v) = d(v) - F(v)$, where $F(v) = \sum_{(x,v)} l(x,v) - \sum_{(v,x)} l(v,x)$. Also set new upperbounds to $c(e) - l(e)$.

Max flow with lower bound (no demands): Binary search on max flow F . Add edge $T \rightarrow S$ with bounds $[F, \infty]$, and set all $d(v) = 0$. Now feasibility implies that a construction with at least F flow exists.

Project Selection Problem: Add source S and sink T . For each project P_i with profit p_i , add $S \rightarrow P_i$ with capacity p_i . For each machine M_i with cost to buy c_i , add $M_i \rightarrow T$ with capacity c_i . For each machines required for a project, add edge $P_i \rightarrow M_j$ with capacity ∞ . Now, $\sum p_i - \text{mincut}$ gives the maximum profit.

7.3 Matching

HopcroftKarp.h

Description: Fast bipartite matching algorithm. Graph g should be a list of neighbors of the left partition, and $btoa$ should be a vector full of -1's of the same size as the right partition. Returns the size of the matching. $btoa[i]$ will be the match for vertex i on the right side, or -1 if it's not matched.

Usage: vi btoa(m, -1); hopcroftKarp(g, btoa);

Time: $\mathcal{O}(\sqrt{VE})$ 728df7, 34 lines

```

bool dfs(int a, int L, vector<vi>& g, vi& btoa
, vi& A, vi& B) {
if (A[a] != L) return 0;
A[a] = -1;
for (int b : g[a]) if (B[b] == L + 1) {
B[b] = 0;
if (btoa[b] == -1 || dfs(btoa[b], L + 1, g
, btoa, A, B))
return btoa[b] = a, 1;
} return 0;
}

int hopcroftKarp(vector<vi>& g, vi& btoa) {
int res = 0;
vi A(g.size()), B(btoa.size()), cur, next;
for (;;) {

Time = ncomps = 0;

```

```
rep(i,0,n) if (comp[i] < 0) dfs(i, g, f);
}

```

76b5c9, 21 lines

BiconnectedComponents.h

Description: Finds all biconnected components in an undirected graph, and runs a callback for the edges in each. In a biconnected component there are at least two distinct paths between any two nodes. Note that a node can be in several components. An edge which is not in a component is a bridge. A node is a cut point if (1) Exists in multiple bccs, or (2) Endpoint of a bridge with degree > 1 (self loops don't count as degree).

Usage: int eid = 0; g.resize(N);
for each edge (a,b) {
g[a].emplace_back(b, eid);
g[b].emplace_back(a, eid++); }
bicomp({&}(const vi& edgelist) { ... });
Time: $\mathcal{O}(E + V)$

De-Brujin Sequence: of order n on a k -size alphabet A is a cyclic sequence in which every possible length n string on A occurs exactly once as a substring. $B(k, n)$ has length k^n and number of distinct sequences is $\{(k!)^{k^{n-1}}\}/k^n$. Find an Euler tour on graph where nodes are $n - 1$ length strings and each node has k outgoing edges for each character.

GrayCode.h

Description: Sequence of binary strings where each successive values differ in only 1 bit. Can be used to find Hamiltonian cycle on n -dimensional hypercube by calling $g(0), \dots, g(2^n - 1)$.

```

int g (int n) { return n ^ (n >> 1); }
int rev_g (int g) { int n = 0;
    for (; g; g >>= 1) n ^= g;
}

```

```

    return n;
}

```

7.5 Coloring

EdgeColoring.h

Description: Given a simple, undirected graph with max degree D , computes a $(D + 1)$ -coloring of the edges such that no neighboring edges share a color. $(D$ -coloring is NP-hard, but can be done for bipartite graphs by repeated matchings of max-degree nodes.)

Time: $\mathcal{O}(NM)$ e210e2, 31 lines

```

vi edgeColoring(int N, vector<pii> eds) {
    vi cc(N + 1), ret(sz(eds)), fan(N), free(N),
        loc;

    return ret;
}

```

7.6 Heuristics

MaximalCliques.h

Description: Runs a callback for all maximal cliques in a graph (given as a symmetric bitset matrix; self-edges not allowed). Callback is given a bitset representing the maximal clique.

Time: $\mathcal{O}(3^{n/3})$, much faster for sparse graphs b0d5b1, 12 lines

```

typedef bitset<128> B;
template<class F>
void cliques(vector<B>& eds, F f, B P = ~B(),
    B X={}, B R={}) {
    if (!P.any()) { if (!X.any()) f(R); return;
    }
}

```

```

auto q = (P | X).FindFirst();
auto cands = P & ~eds[q];
rep(i, 0, sz(eds)) if (cands[i]) {
    R[i] = 1;
    cliques(eds, f, P & eds[i], X & eds[i], R);
    ;
    R[i] = P[i] = 0; X[i] = 1;
}

```

MaximumClique.h

Description: Quickly finds a maximum clique of a graph (given as symmetric bitset matrix; self-edges not allowed). Can be used to find a maximum independent set by finding a clique of the complement graph.

Time: Runs in about 1s for n=155 and worst case random graphs (p=.90). Runs faster for sparse graphs e210e2, 49 lines

```

}

CentroidDecomp.h

```

Description: Divide and conquer on trees. Useful for solving problems regarding all pairs of paths. Simple modifications are needed to integrate TreeBinarize into this.

Usage: Just call decompose(1). ctp[u] = parent of u in ctree. cth[u] = height of u in ctree, root has height = 1. dist[u][h] = original tree distance (u -> ctree ancestor of u at height h).

Time: $\mathcal{O}(N \lg N)$

    *sin(a),x*sin(a)+y*cos(a)); }
friend ostream& operator<<(ostream& os, P p) {
    return os<<"("<< p.x << "," << p.y << ")";
}

```

Description: Returns the shortest distance between point p and the line segment from point s to e.

Usage: Point<double> a, b(2,2), p(1,1);
bool onSegment = segDist(a,b,p) < 1e-10;
"Point.h" 5c88f4, 6 lines

```

typedef Point<double> P;
double segDist(P& s, P& e, P& p) {
    if (s==e) return (p-s).dist();
    auto d = (e-s).dist2(), t = min(d,max(.0,(p-
        s).dot(e-s)));
    return ((p-s)*d-(e-s)*t).dist()/d;
}

```

SegmentIntersection.h

Description:

If a unique intersection point between the line segments going from s1 to e1 and from s2 to e2 exists then it is returned. If no intersection point exists an empty vector is returned. If infinitely many exist a vector with 2 elements is returned, containing the endpoints of the common line segment. The wrong position will be returned if P is Point<ll> and the intersection point does not have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow if using int or long long.

Usage: vector<P> inter = segInter(s1,e1,s2,e2);
if (sz(inter)==1)
cout << "segments intersect at " << inter[0]
<< endl;
"Point.h", "OnSegment.h" 9d57f2, 13 lines

```

template<class P> vector<P> segInter(P a, P b,
    P c, P d) {
    auto oa = c.cross(d, a), ob = c.cross(d, b),
        oc = a.cross(b, c), od = a.cross(b, d);
    // Checks if intersection is single non-
    // endpoint point.
    if (sgn(oa) * sgn(ob) < 0 && sgn(oc) * sgn(
        od) < 0)
        return {(a * ob - b * oa) / (ob - oa)};
    set<P> s;
    if (onSegment(c, d, a)) s.insert(a);
    if (onSegment(c, d, b)) s.insert(b);
    if (onSegment(a, b, c)) s.insert(c);
    if (onSegment(a, b, d)) s.insert(d);
    return {all(s)};
}

```

lineDistance.h

Description:

Returns the signed distance between point p and the line containing points a and b. Positive value on left side and negative on right as seen from a towards b. a==b gives nan. P is supposed to be Point<T> or Point3D<T> where T is e.g. double or long long. It uses products in intermediate steps so watch out for overflow if using int or long long. Using Point3D will always give a non-negative distance. For Point3D, call .dist on the result of the cross product.

"Point.h" f6bf6b, 4 lines

```

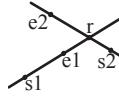

template<class P>
double lineDist(const P& a, const P& b, const
    P& p) {
    return (double) (b-a).cross(p-a) / (b-a).dist()
        ;
}

```

SegmentDistance.h

lineIntersection.h

Description: If a unique intersection point of the lines going through s_1, e_1 and s_2, e_2 exists $\{1, \text{point}\}$ is returned. If no intersection point exists $\{0, (0,0)\}$ is returned and if infinitely many exists $\{-1, (0,0)\}$ is returned. The wrong position will be returned if P is Point<ll> and the intersection point does not have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow if using int or ll.

Usage: auto res = lineInter(s1,e1,s2,e2);
if (res.first == 1)
cout << "intersection point at " <<
res.second << endl;

"Point.h" a01f81, 8 lines

```
template<class P>
pair<int, P> lineInter(P s1, P e1, P s2, P e2) {
    auto d = (e1 - s1).cross(e2 - s2);
    if (d == 0) // if parallel
        return {-(s1.cross(e1, s2) == 0), P(0, 0)};
    auto p = s2.cross(e1, e2), q = s2.cross(e2,
                                             s1);
    return {1, (s1 * p + e1 * q) / d};
}
```

sideOf.h

Description: Returns where p is as seen from s towards e. $1/0/-1 \leftrightarrow$ left/on line/right. If the optional argument eps is given 0 is returned if p is within distance eps from the line. P is supposed to be Point<T> where T is e.g. double or long long. It uses products in intermediate steps so watch out for overflow if using int or long long.

Usage: bool left = sideOf(p1,p2,q)==1;

"Point.h" 3af81c, 9 lines

```
template<class P>
int sideOf(P s, P e, P p) { return sgn(s.cross
    (e, p)); }

template<class P>
int sideOf(const P s, const P e, const P& p,
           double eps) {
    auto a = (e-s).cross(p-s);
    double l = (e-s).dist()*eps;
    return (a > 1) - (a < -1);
}
```

OnSegment.h

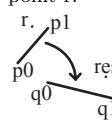

Description: Returns true iff p lies on the line segment from s to e. Use $(\text{segDist}(s,e,p) \leq \text{epsilon})$ instead when using Point<double>.

"Point.h" c597e8, 3 lines

```
template<class P> bool onSegment(P s, P e, P p
) {
    return p.cross(s, e) == 0 && (s - p).dot(e -
        p) <= 0;
}
```

linearTransformation.h

Description: Apply the linear transformation (translation, rotation and scaling) which takes line p0-p1 to line q0-q1 to point r.

"Point.h" 03a306, 6 lines

```
typedef Point<double> P;
P linearTransformation(const P& p0, const P&
    p1,
    const P& q0, const P& q1, const P& r) {
    P dp = p1-p0, dq = q1-q0, num(dp.cross(dq),
        dp.dot(dq));
    return q0 + P((r-p0).cross(num), (r-p0).dot(
        num))/dp.dist2();
}
```

LineProjectionReflection.h

Description: Projects point p onto line ab. Set refl=true to get reflection of point p across line ab instead. The wrong point will be returned if P is an integer point and the desired point doesn't have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow.

"Point.h" b5562d, 5 lines

```
template<class P>
P lineProj(P a, P b, P p, bool refl=false) {
    P v = b - a;
    return p - v.perp()*(1+refl)*v.cross(p-a)/v.
        dist2();
}
```

Angle.h

Description: A class for ordering angles (as represented by int points and a number of rotations around the origin). Useful for rotational sweeping. Sometimes also represents points or vectors.

Usage: vector<Angle> v = {w[0], w[0].t360()
...}; // sorted
int j = 0; rep(i,0,n) { while (v[j] <
v[i].t180()) ++j; } // sweeps j such that (j-i) represents the
number of positively oriented triangles with
vertices at 0 and i

0f0602, 35 lines

```

    - angle a
    int tu = b.t - a.t; a.t = b.t;
    return (a.x*b.x + a.y*b.y, a.x*b.y - a.y*b.x
        , tu - (b < a));
}
```

8.2 Circles

CircleIntersection.h

Description: Computes the pair of points at which two circles intersect. Returns false in case of no intersection.

"Point.h" 84d6d3, 11 lines

```
typedef Point<double> P;
bool circleInter(P a,P b,double r1,double r2,
    pair<P, P*> out) {
    if (a == b) { assert(r1 != r2); return false
        ; }
    P vec = b - a;
    double d2 = vec.dist2(), sum = r1+r2, dif =
        r1-r2,
        p = (d2 + r1*r1 - r2*r2)/(d2*2), h2 =
        r1*r1 - p*p*d2;
    if (sum*sum < d2 || dif*dif > d2) return
        false;
    P mid = a + vec*p, per = vec.perp() * sqrt(
        fmax(0, h2) / d2);
    *out = {mid + per, mid - per};
    return true;
}
```

CircleTangents.h

Description: Finds the external tangents of two circles, or internal if r2 is negated. Can return 0, 1, or 2 tangents – 0 if one circle contains the other (or overlaps it, in the internal case, or if the circles are the same); 1 if the circles are tangent to each other (in which case .first == .second and the tangent line is perpendicular to the line between the centers). .first and .second give the tangency points at circle 1 and 2 respectively. To find the tangents of a circle with a point set r2 to 0.

"Point.h" b0153d, 13 lines

```
template<class P>
```

```
vector<pair<P, P>> tangents(P c1, double r1, P
    c2, double r2) {
    P d = c2 - c1;
    double dr = r1 - r2, d2 = d.dist2(), h2 = d2
        - dr * dr;
    if (d2 == 0 || h2 < 0) return {};
    vector<pair<P, P>> out;
    for (double sign : {-1, 1}) {
        P v = (d * dr + d.perp() * sqrt(h2) * sign
            ) / d2;
        out.push_back({c1 + v * r1, c2 + v * r2});
    }
    if (h2 == 0) out.pop_back();
    return out;
}
```

CircleLine.h

Description: Finds the intersection between a circle and a line. Returns a vector of either 0, 1, or 2 intersection points. P is intended to be Point<double>.

"Point.h" e0cfba, 9 lines

```
template<class P>
vector<P> circleLine(P c, double r, P a, P b)
{
    P ab = b - a, p = a + ab * (c-a).dot(ab) /
        ab.dist2();
    double s = a.cross(b, c), h2 = r*r - s*s /
        ab.dist2();
    if (h2 < 0) return {};
    if (h2 == 0) return {p};
    P h = ab.unit() * sqrt(h2);
    return {p - h, p + h};
}
```

CirclePolygonIntersection.h

Description: Returns the area of the intersection of a circle with a ccw polygon.

Time: $O(n)$

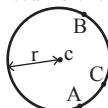

".../content/geometry/Point.h" a1ee63, 19 lines

```
typedef Point<double> P;
#define arg(p, q) atan2(p.cross(q), p.dot(q))

            }
        }
    }
    return {o, r};
}
```

8.3 Polygons

InsidePolygon.h

Description: Returns true if p lies within the polygon. If strict is true, it returns false for points on the boundary. The algorithm uses products in intermediate steps so watch out for overflow.

Usage: vector<P> v = {P{4,4}, P{1,2}, P{2,1}}; bool in = inPolygon(v, P{3, 3}, false);

Time: $\mathcal{O}(n)$

"Point.h", "onSegment.h", "SegmentDistance.h" 2bf504, 11 lines

```
template<class P>
bool inPolygon(vector<P> &p, P a, bool strict =
    true) {
    int cnt = 0, n = sz(p);
    }
```

```
rep(i, 0, n) {
    P q = p[(i + 1) % n];
    if (onSegment(p[i], q, a)) return !strict;
    //or: if (segDist(p[i], q, a) <= eps)
        //return !strict;
    cnt += ((a.y<p[i].y) - (a.y<q.y)) * a.
        cross(p[i], q) > 0;
}
return cnt;
}
```

PolygonArea.h

Description: Returns twice the signed area of a polygon. Clockwise enumeration gives negative area. Watch out for overflow if using int as T!

"Point.h", "sideOf.h" f12300, 6 lines

```
template<class T>
T polygonArea2(vector<Point<T>>& v) {
    T a = v.back().cross(v[0]);
    rep(i, 0, sz(v)-1) a += v[i].cross(v[i+1]);
    return a;
}
```

PolygonCenter.h

Description: Returns the center of mass for a polygon.

Time: $\mathcal{O}(n)$

"Point.h" 9706dc, 9 lines

```
typedef Point<double> P;
P polygonCenter(const vector<P>& v) {
    P res(0, 0), double A = 0;
    for (int i = 0, j = sz(v) - 1; i < sz(v); j =
        i++) {
        res = res + (v[i] + v[j]) * v[j].cross(v[i]);
        A += v[j].cross(v[i]);
    }
    return res / A / 3;
}
```

PolygonCut.h

Description:

Returns a vector with the vertices of a polygon with everything to the left of the line going from s to e cut away.

Usage: vector<P> p = ...;

p = polygonCut(p, P(0,0), P(1,0));

"Point.h", "lineIntersection.h" f2b7d4, 13 lines

```
typedef Point<double> P;
vector<P> polygonCut(const vector<P>& poly, P
    s, P e) {
    vector<P> res;
    rep(i, 0, sz(poly)) {
        P cur = poly[i], prev = i ? poly[i-1] :
            poly.back();
        bool side = s.cross(e, cur) < 0;
        if (side != (s.cross(e, prev) < 0))
            res.push_back(lineInter(s, e, cur, prev).
                second);
        if (side)
            res.push_back(cur);
    }
    return res;
}
```

}

PolygonUnion.h

Description: Calculates the area of the union of n polygons (not necessarily convex). The points within each polygon must be given in CCW order. (Epsilon checks may optionally be added to sideOf/sgn, but shouldn't be needed.)

Time: $\mathcal{O}(N^2)$, where N is the total number of points

"Point.h", "sideOf.h" 3931c6, 33 lines

```
typedef Point<double> P;
double rat(P a, P b) { return sgn(b.x) ? a.x/b.
    x : a.y/b.y; }

    }
    return sgn(l[a].cross(l[b], p)) < r;
}
```

LineHullIntersection.h

Description: Line-convex polygon intersection. The polygon must be ccw and have no collinear points. `lineHull(line, poly)` returns a pair describing the intersection of a line with the polygon: • $(-1, -1)$ if no collision, • $(i, -1)$ if touching the corner i , • (i, i) if along side $(i, i+1)$, • (i, j) if crossing sides $(i, i+1)$ and $(j, j+1)$. In the last case, if a corner i is crossed, this is treated as happening on side $(i, i+1)$. The points are returned in the same order as the line hits the polygon. `extrVertex` returns the point of a hull with the max projection onto a line.

Time: $\mathcal{O}(\log n)$

minkowskiSum.h**LineHullIntersection minkowskiSum ClosestPair kdTree FastDelaunay**

Description: Minkowski sum of two sets $A + B = \{a + b | a \in A, b \in B\}$. P and Q must be ccw oriented polygons. Cool application: Minimum distance between two polygons P and Q in $\mathcal{O}(|P| + |Q|)$. Negate Q and take the sum $P + (-Q)$. Then find shortest distance from $(0, 0)$ to the polygon. If origin is already inside answer is 0, otherwise it is distance between the origin and some edge/vertex.

```

sphericalDistance.h

Description: Returns the shortest distance on the sphere with radius radius between the points with azimuthal angles (longitude) f1 (ϕ_1) and f2 (ϕ_2) from x axis and zenith angles (latitude) t1 (θ_1) and t2 (θ_2) from z axis ($=$ north pole). All angles measured in radians. The algorithm starts by converting the spherical coordinates to cartesian coordinates so if that is what you have you can use only the two last rows. dx*radius is then the difference between the two points in the x direction and d*radius is the total distance between the points.

```
double sphericalDistance(double f1, double t1,
    double f2, double t2, double radius) {
    double dx = sin(t2)*cos(f2) - sin(t1)*cos(f1
        );
    double dy = sin(t2)*sin(f2) - sin(t1)*sin(f1
        );
    double dz = cos(t2) - cos(t1);
    double d = sqrt(dx*dx + dy*dy + dz*dz);
    return radius*2*asin(d/2);
}

        v[x-w[j]] = max(v[x-w[j]], j);
    for (a = t; v[a+m-t] < 0; a--) ;
    return a;
}

```

10.3 Dynamic programming

KnuthDP.h

Description: When doing DP on intervals: $a[i][j] = \min_{i < k < j} (a[i][k] + a[k][j]) + f(i, j)$, where the (minimal) optimal k increases with both i and j , one can solve intervals in increasing order of length, and search $k = p[i][j]$ for $a[i][j]$ only between $p[i][j-1]$ and $p[i+1][j]$. This is known as Knuth DP. Sufficient criteria for this are if $f(b, c) \leq f(a, d)$ and $f(a, c) + f(b, d) \leq f(a, d) + f(b, c)$ for all $a \leq b \leq c \leq d$. Consider also: LineContainer (ch. Data structures), monotone queues, ternary search.

Time: $\mathcal{O}(N^2)$

DivideAndConquerDP.h

Description: Given $a[i] = \min_{lo(i) \leq k < hi(i)} (f(i, k))$ where the (minimal) optimal k increases with i , computes $a[i]$ for $i = L..R-1$.

Time: $\mathcal{O}((N + (hi - lo)) \log N)$

d38d2b, 18 lines

```

struct DP { // Modify at will:
    int lo(int ind) { return 0; }
    int hi(int ind) { return ind; }
    ll f(int ind, int k) { return dp[ind][k]; }
    void store(int ind, int k, ll v) { res[ind] = pii(k, v); }

    void rec(int L, int R, int LO, int HI) {
        if (L >= R) return;
        int mid = (L + R) >> 1;
        pair<ll, int> best(LLONG_MAX, LO);
        rep(k, max(LO, lo(mid)), min(HI, hi(mid)))

```

```

            best = min(best, make_pair(f(mid, k), k));
        }
        store(mid, best.second, best.first);
        rec(L, mid, LO, best.second+1);
        rec(mid+1, R, best.second, HI);
    }
    void solve(int L, int R) { rec(L, R, INT_MIN, INT_MAX); }
};

```

10.4 Debugging tricks

- signal(SIGSEGV, [](int) { _Exit(0); }) converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). _GLIBCXX_DEBUG failures generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).
- feenableexcept(29); kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

10.5 Optimization tricks

`_builtin_ia32_ldmxcsr(40896);` disables denormals (which make floats 20x slower near their minimum value).

10.5.1 Bit hacks

- $x \& -x$ is the least bit in x .
- for (int x = m; ; x = (x - 1) & m)
 // Here x is a submask of m
 if (!x) break;
- $c = x \& -x$, $r = x+c$;
 Now $((x \wedge x) \gg 2)/c \mid r$ is the next number after x with the same number of bits set.
- rep(b, 0, K) rep(i, 0, (1 << K))
 if (i & 1 << b)
 D[i] += D[i^(1 << b)];
 computes all sums of subsets, aka SOS DP.

variableBitset.h

bfc4b2, 8 lines

```

template<int N> void solve(int n) {
    if (n > N) {
        solve<min(2*N, 1'000'000)>(n);
        return;
    }
    // Now solving with bitset<N>;
}
// call solve<1>(n)

```

10.5.2 Pragmas

- `#pragma GCC optimize ("Ofast")` will make GCC auto-vectorize loops and optimizes floating points better.
- `#pragma GCC target ("avx2")` can double performance of vectorized code, but causes crashes on old machines.

• `#pragma GCC optimize ("trapv")` kills the program on integer overflows (but is really slow).

FastMod.h

Description: Compute $a\%b$ about 5 times faster than usual, where b is constant but not known at compile time. Returns a value congruent to $a \pmod{b}$ in the range $[0, 2b)$.

751a02, 8 lines

```

typedef unsigned long long ull;
struct FastMod {
    ull b, m;
    FastMod(ull b) : b(b), m(-1ULL / b) {}
    ull reduce(ull a) { // a % b + (0 or b)
        return a - (ull)((__uint128_t(m) * a) >> 64) * b;
    }
};

```

FastInput.h

Description: Read an integer from stdin. Usage requires your program to pipe in input from file.

Usage: ./a.out < input.txt

Time: About 5x as fast as cin/scanf.

7b3c70, 15 lines

```

inline char gc() { // like getchar()
    static char buf[1 << 16];
    static size_t bc, be;
    if (bc >= be) {
        buf[0] = 0, bc = 0;
        be = fread(buf, 1, sizeof(buf), stdin);
    }
    return buf[bc++]; // returns 0 on EOF
}
int readInt() {
    int a, c;
    while ((a = gc()) < 40);
    if (a == '-') return -readInt();
    while ((c = gc()) >= 48) a = a*10+c-480;
    return a - 48;
}

```

BumpAllocator.h

Description: When you need to dynamically allocate many objects and don't care about freeing them. "new X" otherwise has an overhead of something like 0.05us + 16 bytes per allocation.

745db2, 8 lines

```

// Either globally or in a single class:
static char buf[450 << 20];
void* operator new(size_t s) {
    static size_t i = sizeof(buf);
    assert(s < i);
    return (void*)&buf[i -= s];
}
void operator delete(void*) {}

```

SmallPtr.h

Description: A 32-bit pointer that points into BumpAllocator memory.

2dd6c9, 10 lines

```

template<class T> struct ptr {
    unsigned ind;
    ptr(T* p = 0) : ind(p ? unsigned((char*)p -
        buf) : 0) {
        assert(ind < sizeof buf);
    }
    T& operator*() const { return *(T*)(buf +
        ind); }
};

```

```

T* operator->() const { return &**this; }
T& operator[](int a) const { return (&**this)[a]; }
explicit operator bool() const { return ind; }
};

```

BumpAllocatorSTL.h

Description: BumpAllocator for STL containers.

Usage: vector<vector<int, small<int>>>
ed(N);

bb66d4, 14 lines

```

char buf[450 << 20] alignas(16);
size_t buf_ind = sizeof buf;

```

```

template<class T> struct small {
    typedef T value_type;
    small() {}
    template<class U> small(const U&) {}
    T* allocate(size_t n) {
        buf_ind -= n * sizeof(T);
        buf_ind &= 0 - alignof(T);
        return (T*)(buf + buf_ind);
    }
    void deallocate(T*, size_t) {}
};

```

Unrolling.h

5e0f99, 14 lines

```

#define F {...; ++i;}
int i = from;
while (i & 3 & i < to) F // for alignment, if needed
while (i + 4 <= to) { F F F F }
while (i < to) F

int n32 = n / 32;
while (n32--) {
#define F(i) a[i] = a[i] == x ? y : a[i];
#define FP(i) F(i+0) F(i+1) F(i+2) F(i+3)
    FP(0); FP(4); FP(8); FP(12);
    FP(16); FP(20); FP(24); FP(28);
    a += 32;
}

```

Dates.h

Description: Convert dates to day number and reverse.

b203cf, 18 lines

```

int date_to_int(int y, int m, int d) {
    if (m <= 2) y--, m += 12;
    return 365*y + y/4 - y/100 + y/400 + (153*m
        - 457)/5 + d - 306;
}

```

```

void int_to_date(int z, int &y, int &m, int &d) {
    z += 306;
    int a = z + 68569;
    int b = 4*a/146097;
    a = a - (146097*b + 3)/4;
    int c = 4000*(a + 1)/1461001;
    a = a - 1461*c/4 + 31;
    int e = 80*a/2447;
    d = a - 2447*e/80;
    a = e/11;
    m = e + 2 - 12*a;
    y = 100*(b - 49) + c + a;
}

```

Invariants, Monovariants, whatever-variants,
see what changes and what does not from
start to finish.

Greedy: sorting, matroid, matroid intersection
, add and remove, etc.

Extreme values for greedy: Find the maximum
achievable. Is it always achievable?

Figure out the necessary conditions. Maybe
they are also sufficient (and vice versa)

Fix a parameter and maximize the result wrt
that parameter. Can you binary search
there too?

Construct the lower/upper bounds.

Guess the form, and use induction to prove it.

When asked about how many beautiful things
exist, you must ask how it is beautiful.

Backward solving.

Look at the constraints properly.

Thoroughly read the problem again.

Do your integers fit in int? Convert to long
long when dealing with large bitshifts and
what not. Check constants and single
letter variables.

Try out cases, bruteforce for patterns if pc
is available. If many people solved it, it
is usually something simple. But dont get
stuck in trying to find patterns.

Try to simplify the problem, or solve simpler
cases: functional graphs, DAGs, cycles,
and strongly connected components instead
of directed graphs; trees, cycles, and
biconnected components instead of graphs;
paths instead of trees; 1D instead of 2D;
permutation instead of arrays; etc.

Pigeonhole principle, birthday paradox,
inclusion-exclusion, double counting, etc.

Maybe your idea is fast enough in practice or
maybe your complexity analysis is too
loose.

BFS, DFS, BFS trees, DFS trees, hall-marriage
for bipartite graphs.

Topological sorting can maybe make dp on DAGs
faster or save memory.

Min cut is powerful for stuff like the project
selection problem: n machines with cost
 q_{-i} and m projects with revenue p_{-i} , with
each project requiring a set of machines.

SQRT decomp for time or memory, binary jumping
, and other forms of divide and conquer.
Online MO?

Two-pointer

Offline preprocessing

Bitsets to optimize silly bruteforce

Games: nim, grundy, pattern, etc.

Geometry: isometries and other transformations
(manhattan-to-chebyshev, translations,
rotations, etc), line sweep, radial sweep,
lots of sweeping. Turn other problems
into geometry problems.

Hashing: strings, sets, multisets, rooted
trees, ordered rooted trees, etc. Super
powerful.

String: tries, suffix trees, suffix arrays,
kmp, etc.

Randomization.

HLD, centroid decomp, treaps, seg tree,
persistent seg tree, sliding window, etc.

FFT and friends: generating functions.

DP: memory optimization, CHT, LiChao, D&C,
Knuth, functions as values, aliens trick (for
problems involving partition into k
segments, set a penalty for creating
partitions, then binary search on penalty
value and compare with the optimal
solution where any number of partitioning
is allowed), prefix sum, seg tree, etc.
Remember about boundary cases.

Functional graphs, especially for permutation
problems.

Bitwise or randomized for interactive problems
with logarithmic number of allowed inputs

.
